論 文 題 目 Field Induced Quadrupole Phase Transition in HoTr$_2$Al$_{10}$(Tr=Fe, Ru) under an Orthorhombic Crystal Electric Field
（HoTr$_2$Al$_{10}$(Tr=Fe, Ru)の直方晶結晶場下における磁場誘起四極子相転移）

1. Research background

Recently, physical properties originating from the quadrupole degrees of freedom have been received much attention. Usually, researches of the quadrupole are performed by using compounds with the higher symmetry, such as a cubic symmetry, because an orbitally degenerate state can exist in the crystal electric field (CEF) state. On the other hand, compounds with lower than cubic symmetry have attracted less attention because the orbitally degenerate state is split by the CEF. In this context, an expansion of the study to the lower symmetric compounds is expected in order to discover novel physical properties due to the quadrupole moment.

HoTr$_2$Al$_{10}$ (Tr=Fe, Ru) with the orthorhombic structure is a good candidate which shows the quadrupolar ordering in the low symmetric system. Here, the 4f-electronic state of Ho$^{3+}$ under the orthorhombic CEF is split to 17 singlets. About HoFe$_2$Al$_{10}$, there is no magnetic ordering at 0.1 K at zero magnetic field, which is reported from a neutron scattering experiment. In addition, a specific heat between 0.25 and 3 K shows no sharp peak indicating a phase transition. However, the temperature $T$ dependence of the inverse magnetic susceptibility in polycrystalline HoFe$_2$Al$_{10}$ shows a decrease below 0.25 K, inferring that an ordered state develops at 0.25 K in a magnetic field $H$. Note that the magnitude of $H$ in the experiment was not reported. From the results, there is a possibility of a field induced phase transition due to a quasi-degenerate state in HoFe$_2$Al$_{10}$. On the other hand, HoRu$_2$Al$_{10}$ shows an antiferromagnetic (AFM) phase transition at $T_N$=5.0 K at zero magnetic field. The phase transition at $T_N$ arises from a quasi-degenerate state. Considering the multipole degrees of freedom of the quasi-degenerate state, the quadrupole degrees of freedom may exist in the quasi-degenerate state of HoTr$_2$Al$_{10}$ because the number of the degrees of freedom in the quasi-degenerate state is 3 (=2×2-1) at least. However, there has been no investigation about the quadrupole ordering in HoTr$_2$Al$_{10}$ so far. In the present study, to investigate the quadrupolar ordering in the orthorhombic compound HoTr$_2$Al$_{10}$, measurements of the specific heat, magnetization, and elastic modulus were carried out.

2. Research results

【HoFe$_2$Al$_{10}$】
In HoFe$_2$Al$_{10}$, transverse modulus $C_{55}$ shows an elastic softening down to 0.5 K without any anomaly at zero magnetic field, suggesting that no phase transition above 0.5 K. However, under $H$ along the $a$- and $c$-axes, the softening of $C_{55}$ in 0.6 (0.4) T stops at $T_Q=0.8$ (0.75) K for $H//a$ ($c$). With further increasing $H//a$ and $c$, the magnitude of the softening toward $T_Q$ in $C_{55}$ is enhanced. From the results, the $H$-$T$ diagrams of the magnetic field induced phase transition (FIP) for $H//a$ and $c$ were confirmed in HoFe$_2$Al$_{10}$. $T_Q$ exhibits a reentrant behavior with respect to $H//a$ and $c$. Since $C_{55}$ is the modulus corresponding to quadrupole $O_{zx}$, the enhancement of the elastic softening toward $T_Q$ in $C_{55}$ under $H$ suggests that the FIP is the field induced $O_{zx}$-type quadrupolar ordering. The CEF calculation for the specific heat, magnetization, and elastic modulus shows the approach between the CEF ground and first excited singlet with increasing $H//a$ and $c$, suggesting a formation of a quasi-degenerate state. Here, there is the interlevel transition of $O_{zx}$ between them. In this sense, the field induced quadrupolar (FIQ) ordering in HoFe$_2$Al$_{10}$ probably originates from the enhancement of the expected value for $O_{zx}$ by the formation of the quasi-degenerate state.

[HoRu$_2$Al$_{10}$]

The step like softening at $T_N$ in longitudinal moduli $C_{11}$, $C_{22}$, and $C_{33}$, and hardening of all moduli below $T_N$, which can be explained by the thermodynamic relation between the elastic moduli and the magnetic ordering, were observed in HoRu$_2$Al$_{10}$ at zero magnetic field. In addition, $H$-$T$ diagrams for $H//a$, $b$, and $c$ were determined from the measurements of the specific heat, magnetization, and elastic modulus. In $H//b$, $T_N$ decreases monotonically with increasing $H$, and the phase boundary closes around 1.0 T, which is a usual behavior originating from a competition between the Zeeman effect and the spin interaction. In contrast, under $H//a$ and $c$, although $T_N$ decreases with increasing $H$, the phase boundary shows an inflection point around 5.0 T. Meanwhile, the remarkable softening of $C_{11}$, $C_{22}$, and $C_{33}$ toward $T_N$ is induced under $H//c$ above 8 T, which is not observed in the low $H$ range. Since $C_{11}$, $C_{22}$, and $C_{33}$ are included in an elastic mode $(C_{11}+2C_{12}+4C_{13}+C_{22}+4C_{23}+4C_{33})/12$ which is corresponding to quadrupole $O_{2z}^0$, the field induced softening in $C_{11}$, $C_{22}$, and $C_{33}$ suggests that the $O_{2z}^0$-type quadrupolar ordering emerges in high $H//c$. The FIQ ordering may be expected in the high $H//a$ because the magnetic anisotropy between the $a$- and $c$- axes is small. From the view point, the inflection point of the phase boundary in $H//a$ and $c$ is assumed to the result of the phase transition from the AFM ordering in the low $H$ range to the FIQ ordering in the high $H$ range. However, for $H//a$ and $c$, any clear anomaly which indicates the phase boundary between the AFM ordering and FIQ ordering were not observed in this study, suggesting that there is a crossover between the higher and lower $H$ range.

3. Summary

In the present study, the measurements of the specific heat, magnetization, and elastic modulus were performed on HoTr$_2$Al$_{10}$ with the orthorhombic symmetry to investigate the ordered state in
HoTr₂Al₁₀. In the experiments, the enhancement of the elastic softening under $H \parallel a$ and $c$ was observed in HoTr₂Al₁₀, suggesting that the FIQ ordering emerges by applying $H \parallel a$ and $c$. The order parameters of the FIQ phase in HoFe₂Al₁₀ and HoRu₂Al₁₀ are probably $O_{zx}$ and $O_{2\beta}$, respectively. This is the first report on the FIQ ordering in the compounds with the orthorhombic symmetry.
