Received October 30, 1992

Abstract A total of 242 non-anguillid leptocephali was collected in the coastal water (20-60 m deep) around the Tanegashima Island, especially in the southern and western coasts. The dominant was *Gnathophis nystromi nystromi* (54.5%). The species was caught in any depth and at any time in the coastal water. Many oceanic larvae and juveniles of non-Auguilliformes fishes were also captured. Hydrographic characteristics including temperature and salinity of the coastal water showed that the water was extremely homogeneous horizontally and vertically, and was very similar with the Kuroshio water in quality. All the data obtained in the present study imply that the Kuroshio Current flows directly into the coastal water of the island and transports many oceanic larvae and juveniles of fish species there. Routes of the coastal migration of *Anguilla japonica* could not be clarified.

Key-words: *Anguilla japonica*, coastal migration, fish larvae, Kuroshio Current, leptocephali, Tanegashima Island.

INTRODUCTION

A whole life history of the Japanese eel *Anguilla japonica* has remained a mystery even after the spawning area of the Atlantic eels *A. anguilla* and *A. rostrata* had been outlined by SCHMIDT (1922, 1925). Quite recently the spawning area of the Japanese eel has been estimated to be in the North Equatorial Current from 14° to 16°N and 134° to 143°E on the south side of a salinity front by collections of significant numbers of the smallest leptocephali in that area (TSUKAMOTO 1992).

However, both recruitment strategies of the Japanese eel from the spawning area to the Kuroshio Current and from the Kuroshio to coastal waters are still unknown (TSUKAMOTO 1990). The periods are missing links left to be clarified in the life history of the Japanese eel. The present study was planned (1) to know the ichthyofauna surrounding the migrating

routes of *A. japonica*, (2) to clarify the routes, and finally (3) to determine the recruitment mechanisms of the glass eels to coastal waters. In this paper we report preliminarily the collection records of leptocephali and other fish larvae during two cruises conducted in 1991 around the Tanegashima Island.

MATERIALS AND METHODS

Samplings were carried out during TS-91-10 cruise of T. V. Toyoshio Maru of Hiroshima University between November 7 and 15, and during KT-91-16 cruise of R. V. Tansei Maru of Ocean Research Institute, University of Tokyo between December 6 and 18. Three main collecting lines were placed at right angles to coastal lines of the east, south and west coasts of the Tanegashima Island and some supplemental collecting lines

were also used (Fig. 1). Fish was collected by several consecutive oblique tows between bottom and surface and step tows with 6 ft. and 10 ft. Issacs-Kidd Midwater Trawl (IKMT, mesh aperture 1.0 mm), and horizontal surface and bottom tows with a larva net (mesh aperture 0.33 mm, mouth opening 1.33 m²), an ORI net (mesh aperture 1.0 mm, mouth opening 2.00 m²) and a 1.45 m sleigh net (mesh aperture 0.33 mm) for 15–20 min by day and night (Tables 1 and 2). Wire length of the oblique tows, step tows and bottom tows were 40–190 m. Step tows were conducted in the three depths (surface, middle and bottom; each 10 min). Six dredges (0.5 m span-ORI type, mesh aperture 4.0 mm) were also carried out in the place of 30–130 m deep (Table 2). Water temperature and salinity were measured with STD or CTD at every 1 m from the surface to the bottom at each station.

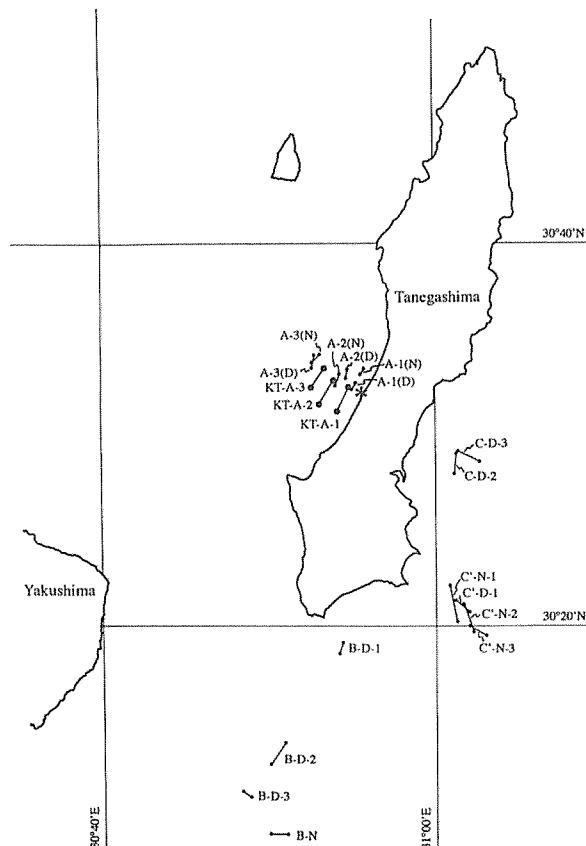

Fig. 1 Sampling stations in the present study. St-As and St-KT-As were located at the mouth of the Ihara River (asterisks). St-Bs and St-Cs were located in the southern and the eastern coasts of the Tanegashima Island, respectively. Sampling areas in the eastern coast were shifted south on account of stormy weather and the stations were named St-C's. St-KT-As were surveyed in KT-91-16 and other stations were used in TS-91-10.

At night on November 12th and December 11th, collection of *Anguilla* glass eels approaching the river mouth was carried out with a hand-net along the Nagahama

Beach besides the mouth of the Ihara River (facing to the collecting line A) (asterisk in Fig. 1).

Leptocephali and fish larvae were preserved in 10% neutralized formalin. Identification of leptocephali and fish larvae was from OKIYAMA (1988).

RESULTS AND DISCUSSION

A total of 242 Anguilliformes leptocephali were collected by step and oblique tows of IKMT during day- and night-time, and by horizontal surface and bottom tows of the larva

net and the ORI net during night time at the stations around the Tanegashima Island (Tables 1-4). However, no anguillid leptocephali and glass-eels were found among them. The depth of each station was ranged 10-114 m. All the leptocephali were belonged to the order Anguilliformes including Congridae, Dysommatidae, Muraenidae, Nettastomatidae and Ophichthidae (Tables 3 and 4). Congridae consisted of *Gnathophis nystromi nystromi* (132 specimens), *Ariosoma*-sps. including sp.5, sp.7 and others (45 specimens) and Congrinae-sps. including Congrinae sp.1 and others (7 specimens) (Tables 3 and 4). Dysommatidae specimens were identified to be *D. anguillare*. Nettastomatidae were *S. lateromaculatus* and *S. stylurus*. Others were identified to spp. levels.

G. n. nystromi is a dominant species among the leptocephali collected in the present study, and occupies 41% and 56% of the total catches in TS-91-10 and KT-91-16, respectively. The species was collected at most stations in the western and southern coasts of the island of 20-60 m deep by surface tows and oblique or step tows during both day- and night-time. Many *G. n. nystromi* had been collected in the open sea and the Kuroshio Current (TABETA and MOCHIOKA 1988, UEMATSU et al. 1990). Upon these observations, we

speculate that the leptocephali were transported by the Kuroshio Current from the open sea to sea shore around the Tanegashima Island. The results that many oceanic larvae and juveniles of *Bathylagus ochotensis*, *Gonorynchus abbreviatus* and *Myctophiae* spp. were caught in coastal area also support this view (Tables 5-10). Glass eels or leptocephali of the *Anguilla japonica* should also approach the Tanegashima Island along the Kuroshio Current like other fish larvae and juveniles. Most leptocephali usually distribute in the surface layer shallower than 100 m in the ocean (CASTONGUAY and McCLEAVE 1987). Water temperature in the stations measures ranged between 22.7-24.3°C in TS-91-10 and between 20.2-22.1°C in KT-91-16, and vertical differences were usually smaller than 0.3 degrees in every station shallower than 100 m. Salinity in the survey area was constant vertically and horizontally and ranged between 34.5-34.7‰ in TS-91-10 and between 34.6-34.9‰ in KT-91-16. The distribution of the leptocephali, and the horizontally and vertically constant

temperature and salinity in the survey area may imply that the surface water of the Kuroshio containing leptocephali might be thrusted into shallower coastal area as approaching the island, since the temperature and salinity of the Kuroshio Current between 0-100 m depth were similar values as those observed during the two cruise (temperature and salinity in October, 1988*, and temperature in November and December, 1991**).

More than 600 *Anguilla* glass eels were collected at the Nagahama Beach by four persons between 19:30 and 20:30 on November 12. Seven lightly pigmented glass eels were also collected from bottom sand in the Ihara River at a point about 100 m up the river mouth on 11th December. Although we failed in collection of *Anguilla* glass eels on board in spite of our desperate collecting efforts, recruiting glass eels had been approached the beach keeping away from our fishing gears. New collecting devices alternative to the bottom dredge and the bottom larva net must be needed.

Acknowledgement We thank T. SHIMA, K. HIRAHARA, A. NAKAJIMA, A. WANISHI, M. YAMADA, S. ABE, Y. KONDO, C. MUROMOTO, H. TOMODA, T. YASUOKA, students of Faculty of Applied Biological Science, Hiroshima University, and N. MIZUNO of Fisheries Laboratory, the University of Tokyo for their assistance in the cruises. Thanks are also due to the Captain Y. FUKUURA and the crew of R. V. Toyoshio Maru, and the Captain K. UENO and the crew of R. V. Tansei Maru for their kind support at sea.

種子島周辺に出現したレプトケファルス幼生とその他の仔稚魚 ——特に黒潮とニホンウナギの接岸回遊との関連について——

植松 一眞^{*1}・大竹 二雄^{*2}・塙本 洋一^{*2}
 阪倉 良孝^{*2}・黒倉 寿^{*3}
 蓮本 浩志^{*2}・塙本 勝巳^{*2}

^{*1} 広島大学生物生産学部, 広島県東広島市 724

^{*2} 東京大学海洋研究所, 東京都中野区 164

^{*3} 東京大学農学部付属水産実験所, 静岡県浜名郡 431-02

種子島沿岸での, 1991年11月（広島大学豊潮丸）および12月（東京大学淡青丸）の採集により, 計242尾のウナギ目レプトケファルス幼生と計5520尾の他目の仔稚魚が採集された。ニホンウナギの幼生は採集されなかった。採集されたレプトケファレス幼生の54.5%をギンアナゴ *Gnathophis nystromi nystromi* が占めた。ギンアナゴ幼生は種子島の西岸および南岸の水深 100-10 m の測点で, 水深や昼夜を問わず採集された。ギンアナゴ幼生, および他目の仔稚魚の中で優先したネズミギス *Gonorynchus abbreviatus*・ソコイワシ *BathyLAGUS ochotensis*・ハダカイワシ科 *Myctophidae* spp. は, いずれも通常は沖合い水域に出現する魚種である。当該海域の水温・塩分濃度は表層から底層まで極めて均一であり, しかも同じ時期の黒潮の水温・塩分濃度とよく一致した。以上より, 種子島の西岸と南岸には黒潮水が直接流れ込むことが明らかとなった。沖合い性の仔稚魚は黒潮によって運ばれ, 種子島沿岸に達するものと推察される。同時に運行なわれた, 種子島西海岸長浜なぎさにおける採集では多数のニホンウナギのシラスが採集された。

キーワード: 黒潮, 接岸回遊, 種子島, 仔稚魚, ニホンウナギ, レプトケファルス幼生
