**Abstract**

**Objective:** To evaluate the one step technique compared with the Seldinger technique in computed tomography (CT) fluoroscopy-guided percutaneous drainage of abdominal and pelvic abscess.

**Material and methods:** Seventy six consecutive patients (49 men, 27 women; mean age 63.5 years, range 19-87 years) with abdominal and pelvic abscess were included in this study. Drainages were performed with the one step (n=46) and with the Seldinger (n=48) technique between September 2012 and June 2014.

**Results:** The technical success and clinical success were 95.8% and 93.5%, respectively, for the one step group, and 97.8% and 95.7%, respectively, for the Seldinger group. The mean procedure time was significantly shorter with the one step than with the Seldinger method ( $15.0 \pm 4.3$  min, range 10 - 29 min vs  $21.0 \pm 9.5$  min, range 13-54 min,  $p < 0.01$ ). The mean abscess size and depth were  $73.4 \pm 44.0$  mm and  $42.5 \pm 19.3$ mm, respectively, in the one step group, and  $61.0 \pm 22.8$  mm and  $35.0 \pm 20.7$  mm in the Seldinger group.

**Conclusion:** The one step technique was easier and faster than the Seldinger technique. The effectiveness of both techniques was similar for the CT fluoroscopy-guided percutaneous drainage of abdominal and pelvic abscess.

## Introduction

Percutaneous drainage under imaging guidance is effective and, in combination with broad-spectrum intravenous antibiotics, it is the standard treatment for intra-abdominal and intrapelvic abscesses (1-3). Percutaneous catheter drainage under image guidance is now the primary treatment for such abscesses (4); the reported abscess cure rates are 80%-91.0% (2, 5-8). Percutaneous drainage has been performed under ultrasonography and fluoroscopy, computed tomography (CT), and CT-fluoroscopy (9-11). Catheters can be inserted using either the one step technique or the Seldinger technique. As the difference between these techniques remains to be evaluated, we compared the ease and effectiveness of the one step and the Seldinger technique in the (CT) fluoroscopy-guided percutaneous drainage of abdominal and pelvic abscesses.

## Material and methods

Approval for this research was obtained from the institutional ethics committee. Principles of the Declaration of Helsinki were followed. Informed consent for the procedure was obtained from all patients.

### *Patients*

1  
2  
3  
4  
5  
6 Between September 2012 and June 2014, CT fluoroscopy-guided percutaneous  
7  
8 drainage was carried out on 76 patients (49 men, 27 women; mean age 63.5 years, range  
9  
10 19-87 years) with 94 procedures. Twenty-three abscesses were retroperitoneal, 48  
11  
12 abscesses were intraperitoneal, 21 abscesses were pelvic. In all cases, 7- to 8-Fr  
13  
14 drainage catheters were used.  
15  
16  
17  
18  
19

20 Between September 2012 and May 2013, all procedures were performed with  
21  
22 the Seldinger technique. Between June 2013 and June 2014, almost all procedures were  
23  
24 performed with the one step technique.  
25  
26  
27

28 The suspicion of a fluid collection was based on clinical and laboratory  
29  
30 findings and confirmed by CT. Patients had received empirical treatment with a  
31  
32 broad-spectrum antibiotic before undergoing the procedure. Treatment was  
33  
34 subsequently modified after CT guided percutaneous drainage on the basis of the  
35  
36 antibiogram of the fluid aspirated during the drainage procedure.  
37  
38  
39  
40  
41  
42

43 Preliminary helical CT images were obtained with the skin marker in place on  
44  
45 3 mm-thick sections through the lesion. Based on these images we determined the  
46  
47 appropriate patient position (supine, prone, or lateral), the level of the needle entry site,  
48  
49 and the direction of the approach yielding the best direct route for drainage while  
50  
51 avoiding the intestines, major blood vessels, and other important organs.  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 In the one step technique, an 18- gauge needle was advanced under CT  
7  
8  
9 fluoroscopic guidance into the fluid collection. The inner stylet of the needle was  
10  
11 removed and a fluid sample was aspirated to confirm satisfactory placement of the  
12  
13 needle within the collection. Then a self-retaining locking 7 or 8 Fr pigtail catheter with  
14  
15 a distal hydrophilic tip (Hydrophilic Drainage Catheter, Bioteque, Taipei, Taiwan)  
16  
17 attached to a metal stiffener was advanced in parallel and approximately 5 mm adjacent  
18  
19 to the 18- gauge needle to the appropriate depth. The catheter was then released from  
20  
21 the metal stiffener and advanced into the fluid collection. Finally, CT imaging was  
22  
23 obtained to confirm catheter position. With the catheter in place, the abscess cavity was  
24  
25 aspirated with a syringe and the abscess was allowed to drain by gravity. In some cases,  
26  
27 the position of the catheter tip was fine-tuned using a guidewire under fluoroscopy  
28  
29 (Figure 2 a-d).  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39

40 In the Seldinger technique, the fluid collection was punctured with an 18-  
41  
42 gauge needle under CT fluoroscopic guidance. With the needle tip in the collection, the  
43  
44 inner needle was withdrawn and a small quantity of fluid was aspirated. A 0.035 inch  
45  
46 guide wire was inserted under guidance by CT fluoroscopy or fluoroscopy. A 7- or 8- Fr.  
47  
48 pigtail catheter (Dawson-Mulleller Drainage Catheter, Cook, USA or CLINY, Create  
49  
50 Medic, Yokohama, Japan) was advanced after track dilatation with gradual dilators.

1  
2  
3  
4  
5  
6 After proper positioning of the catheter was confirmed by CT fluoroscopy, final CT  
7  
8  
9 images were obtained to confirm its position. A syringe was used to aspirate the abscess  
10  
11  
12 cavity and the abscess was then allowed to drain by gravity.

### 13 14 *Parameters investigated*

15  
16  
17 The following parameters were retrospectively investigated by three authors in  
18  
19  
20 consensus: technical success, clinical success, procedure time, additional treatment, and  
21  
22  
23 complication.

24  
25  
26 Technical success was defined as the catheter having been successfully inserted  
27  
28  
29 into the fluid collection. Clinical success was defined as a reduction in the abscess size  
30  
31  
32 on follow-up images with improvement in leukocytosis, fever, and the clinical condition.

33  
34  
35 Procedure time was defined as the duration from initial localization of the abscess on  
36  
37  
38 the preliminary CT image to the final CT scan confirming the catheter location.

39  
40  
41 Procedural complications were recorded according to the Society of Interventional  
42  
43  
44 Radiology clinical practice guideline.

45  
46  
47 The drainage interventions were performed using an interventional-CT system  
48  
49  
50 featuring a unified 16-row multidetector CT scanner and an angiography unit (Aquilion  
51  
52  
53 LB combined with Infinix Celeve-i INFX-8000V, Toshiba Medical Systems Tokyo,  
54  
55  
56 Japan). During the CT fluoroscopic drainage, the exposure parameters were 120 kV,  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 20-40 mA, a slice thickness of 4 mm, and scanning speed of 0.5 s per rotation. The  
7  
8  
9 operator in the CT room wore a protective lead apron and controlled CT fluoroscopic  
10  
11 exposure via a foot pedal and assisted in gantry movement and directed the laser light  
12  
13 beam via a control panel. Real-time imaging was limited to narrow range to visualize  
14  
15 the position of the advancing needle tip.  
16  
17  
18

### 19 20 21 *Statistical analysis*

22  
23 The Mann–Whitney U test was performed to assess statistical differences in  
24  
25 mean values, and the Fisher's exact test was performed to evaluate for significant  
26  
27 differences in categorical data. A value of  $p < 0.05$  was considered significant.  
28  
29  
30  
31  
32  
33  
34

### 35 **Results**

36  
37  
38 Of the total of 94 percutaneous abscess drainage catheters placed in 76 patients,  
39  
40 39 patients with 48 procedures were performed with the one step technique, 37 patients  
41  
42 with 46 procedures were performed with Seldinger technique. Between June 2013 and  
43  
44 June 2014, we performed percutaneous drainage with the one step techniques for all  
45  
46  
47 patients with three exceptions. Two cases were performed by drainage via the  
48  
49  
50 transthoracic approach using the Seldinger technique to avoid iatrogenic lung puncture  
51  
52  
53 (Figure 3 a-c). In another patient with a small abscess close to the rectum we thought it  
54  
55  
56  
57  
58  
59  
60

necessary to advance the catheter more accurately by using the Seldinger technique.

Of the 39 patients undergoing the one step procedure, 25 (64.1%) had developed abscesses after surgery, 22 (56.4%) had a history of cancer, and 14 (35.9%) had an inflammatory disease (e.g. pancreatitis, inflammatory bowel disease, diverticulitis, iliopsoas muscle abscess). The mean abscess size and depth were  $73.4 \pm 44.0$  mm and  $42.5 \pm 19.3$ mm, respectively. The technical and clinical success rates for the one step procedure were 95.8% (46/48) and 93.5% (43/46), respectively. There were two technical failure cases, the reasons were inability to deploy the catheter, and one abscess cavity was small and it was not possible to deploy the catheter. CT guided drainage was performed again with the Seldinger technique for this case. There were no procedure-related complications such as bowel perforation or bleeding, necessitating surgical intervention. The mean duration of catheter drainage was  $12.0 \pm 63.7$  days. Additional treatment was required in 11 patients (29.7%); six patients needed additional drainage utilizing the same initial technique and five needed surgery. The mean procedure time was  $21.0 \pm 9.5$  min (range 13 - 54 min).

Among the 37 patients in the Seldinger group, 26 (70.3%) developed abscesses after surgery; 18 (48.6%) had a history of cancer, and 12 (32.4%) had an inflammatory disease. The mean size and depth of the abscess were  $61.0 \pm 22.8$  mm and  $35.0 \pm 20.7$

## 10 11 12 **Discussion**

13  
14 The development of image-guided percutaneous treatment in the early 1980s  
15 rendered percutaneous treatment and catheter drainage procedures possible and the  
16 management of abdominal and pelvic abscesses has moved strongly toward nonsurgical  
17 methods (12, 13). In the absence of immediate surgical indications, percutaneous  
18 catheter drainage and antibiotics are considered by many the treatment of choice for  
19 most abdominal and pelvic abscesses, primarily because this type of treatment is  
20 effective and avoids the risks of general anesthesia and surgery. The usefulness of  
21 percutaneous drainage for abdominal and pelvic abscesses is well known. Lambiase et  
22 al. (6) successfully performed drainage of abdominal and pelvic collections in 91%  
23 (305/335) of procedures, Akinci et al. (10) did so in 91.0% (273/300) of procedures, and  
24 Cinat al. (8) did so in 82.2% (79/96) of procedures.

28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45

46  
47 Ultrasound guidance has been widely used to address intra-abdominal and  
48 intra-pelvic fluid collections. It is the easiest, fastest way to visualize such collections,  
49 allows real-time imaging, and is portable. On the other hand, CT studies can  
50 demonstrate the extent of the abscess and facilitate selection of a safe route to the  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 abscess to avoid injury to the bowel and large blood vessels. While CT-fluoroscopy  
7  
8  
9 overcomes the impossibility of real-time imaging by conventional CT methods  
10  
11 (11,14-16) it can only scan a narrow area. The entirety of the guidewire used in the  
12  
13 Seldinger technique cannot be imaged by CT-fluoroscopy due to its long length and  
14  
15 sweeping form.  
16  
17  
18

19  
20 The one step technique is advantageous when CT fluoroscopy is employed.  
21  
22 The stiffness of the catheter-cannula-stylet combination allows for more directional  
23  
24 control of the catheter (9), it does not require serial dilation, and placement can be  
25  
26 performed in a single step. Consequently, the one step technique is faster than the  
27  
28 Seldinger technique (17). However, there are some disadvantages: Repositioning of the  
29  
30 catheter in cases of malpositioning is difficult and the one step technique is not optimal  
31  
32 in patients with small abscesses because the catheter tip may move upon withdrawal of  
33  
34 the inner stylet of the needle. Although the Seldinger technique is safer than the one step  
35  
36 technique because the external cylinder is smaller (12, 18), it is cumbersome and in  
37  
38 institutions that do not have a unified CT/angiography system, the patient must be  
39  
40 moved from the CT- to the fluoroscopy room. In our hands, the mean procedure time  
41  
42 was significantly shorter with the one step technique than with the Seldinger technique  
43  
44 (15.0 ± 4.3 min, range 10 - 29 min vs. 21.0 ± 9.5 min, range 13 - 54 min, p < 0.01).

57  
58  
59  
60

1  
2  
3  
4  
5  
6 mm, respectively. The technical and clinical success rates were 97.8% (46/47) and  
7  
8  
9 95.7% (44/46), respectively. Technical failure in one patient was due to bending of the  
10  
11 guidewire that disallowed introduction of the catheter. This patient was subsequently  
12  
13 treated with the one step technique. There were no procedure-related complications.  
14  
15  
16 Mean catheter drainage duration was  $25.0 \pm 57.3$  days. Additional treatment was  
17  
18 required for 11 patients (29.7%); six patients needed additional drainage utilizing the  
19  
20 same initial technique and five patients needed surgery. The mean procedure time was  
21  
22  
23  
24  
25  
26  
27 21.0  $\pm$  9.5 minute (range 13 - 54 minute).  
28

29  
30 The characteristics of the 76 patients who underwent 94 procedures are  
31  
32 summarized in Table 1. The two patients groups had similar demographic and baseline  
33  
34 clinical characteristics. The demographics and baseline clinical characteristics of the  
35  
36 patients treated with the Seldinger or the one step procedure were similar, as were the  
37  
38 prognostic procedure-related variables including the size, depth and location of the  
39  
40 lesions ( $p > 0.05$ ) and the overall technical success rate, the clinical success rate, the  
41  
42 rate of complications, and the need for additional treatment. On the other hand, the  
43  
44 mean procedure time was significantly shorter ( $p < 0.01$ ) in the one step group than in  
45  
46 the Seldinger group ( $15.0 \pm 4.3$  min, range 10 - 29 min vs.  $21.0 \pm 9.5$  min, range 13 - 54  
47  
48 min). The one step technique required 28.6% less time per drainage than the Seldinger  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 Overall, the one step technique required 28.6% less time per drainage than the more  
7  
8  
9 complex Seldinger technique which, unlike the one step method, may require moving  
10  
11 the patient for CT and fluoroscopy studies. Our overall technical and clinical success  
12  
13 rates were 95.8% (46/48) and 93.5% (43/46), respectively, in patients treated with the  
14  
15 one step procedure. These rates were 97.8% (45/46) and 95.6% (43/45) when we used  
16  
17 the Seldinger method. As these rates were not significantly different between the two  
18  
19 procedures, we suggest that the one step technique is appropriate in most instances. In  
20  
21 fact, in 49 cases for which drainage procedure was performed during the period when  
22  
23 the one step technique was used as the first choice (i.e., from June 2013 to June 2014),  
24  
25 there are only three cases for which we chose the Seldinger technique; this shows that  
26  
27 one step technique was possible in most cases. Hence, we should choose the Seldinger  
28  
29 technique if necessary for cases in which procedures using the one step technique is  
30  
31 considered undoubtedly difficult.  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43

44 Our study has some limitations. Its design was retrospective and observational.  
45  
46 The two groups were not strictly randomized using a computerized randomization  
47  
48 program.  
49  
50

51  
52 In conclusion, we suggest that the one step technique is easier and faster than  
53  
54 the Seldinger technique for the percutaneous CT fluoroscopy-guided drainage of  
55  
56

21 **Figure 2**  
22

23 A 63-year-old man two weeks after surgery for rectal cancer: (a) Enhanced CT showed a  
24 presacral abscess that originated from a postsurgical fluid collection (arrow). (b,c) The  
25 drainage tube was inserted with the one step technique. The patient was in the prone  
26 position. (d) The drainage tube was removed eight days after the one step procedure.

The enhanced CT image acquired three months later shows complete resolution of the  
fluid collection (arrow).

61  
62 **Figure 3**  
63

64 A 34-year-old man with an immunosuppressive disease: Enhanced CT image showing a  
65 subphrenic abscess without a fistula (arrow). (b) The abscess was punctured with an  
66 18-gauge needle and a 0.035 inch guide wire was inserted under guidance by CT  
67 fluoroscopy. (c) The drainage tube was inserted via the transthoracic approach using the  
68 Seldinger technique.  
69  
70

Table 1 Demographic and baseline comparison between the one step and the seldinger group with 76 patients

Characteristics	One step <i>N</i> =39	Seldinger <i>N</i> =37	<i>P</i> values
Sex			
Male	25	24	0.944
Female	14	13	
AGE (years)	66±19.5	61±16.6	0.1878
Lesion size (mm)	73.4±44.0	61.0±22.8	0.38 25
Lesion depth (mm)	42.5±19.3	35.0±20.7	0.0849
Location			
intraperitoneal	22	28	0.1012
retroperitoneal	11	12	
pelvic	15	6	
Postsurgical abscess	25	26	0.5673
Underlying disease			
Cancer	22	18	0.4982
Inflammatory disease	14	12	0.7503

Table 2 Procedure and outcome variable comparisons between the one step and the Seldinger group of 94 procedures

Characteristics	One step	Seldinger	<i>P</i> values
Technical success rate	95.8% (46/48)	97.8% (45/46)	0.5826
Clinical success rate	93.5% (43/46)	95.6% (43/45)	0.6812
Procedure-related complications	0	0	1
Additional treatment	12/39	11/37	0.90247
duration of catheterization (days)	12.0±63.7	25.0±57.3	0.1934
Procedure time (min)	15.0±4.3	21.0±9.5	<0.01
